

## INSTALLATION NOTES & GUIDELINES FOR MAC OS X

---

### BEFORE INSTALLATION

---

- Disconnect the usb Cressi interface, as well as other similar usb devices – there is no need to disconnect external usb drives or other storage media
- Check and take note of your OS version by clicking on the top left menu "apple" -> About this Mac, or running Utilities -> System Information.app
- Two kinds of installation packages are available - one kind for full installation, and one for upgrade only. If you already have a fully functional version of the Cressi PC Interface application on your system, you only need to download an "upgrade" installation package. If not, you'll have to use a "full" installation package instead
- Download the dmg file that matches your needs (upgrade or full) and your OS X version.  
WARNING: a wrong choice may result in a nonfunctional installation.
- Make sure that your system accepts applications downloaded from Anywhere (check under "apple" -> System Preferences -> Security & Privacy -> General)

### INSTALLATION STEPS FOR MAC OS X 10.7 TO 10.9

---

- The dmg file contains the installation package: if your settings allow file extensions display, you'll see it as mpkg file - the associated icon resembles a cardboard box.
- Double click on the package - the installation process will start
- Choose "standard install" when asked for installation type
- You may get a system message referring to "lipo command", and offering the option to install Xcode-related packages - choose not to install them, and disregard the message
- After installation, reboot the system
- After rebooting, the usb interface can be reconnected

### INSTALLATION STEPS FOR MAC OS X 10.10 YOSEMITE

---

- The dmg file contains two installation packages: if your settings allow file extensions display, you'll see them as mpkg files - the associated icon resembles a cardboard box. Observe the package names:

"1\_CressiPCInterface\_1\_3\_0\_Pre\_Installation" is the "PREinstaller" and it has to be installed first for the latest OS X 10.10 version;

the 2nd, either "2\_CressiPCInterface\_1\_3\_0\_Full\_Installation" or "2\_CressiPCInterface\_1\_3\_0\_Upgrade", is the "real installer" and it has to be executed after the PREinstaller

- So, the sequence you have to follow is:

run the "PREinstaller";

reboot your system;

run the (upgrade or full) "installer"

reboot your system again;

- WARNING: Using the packages out of sequence will result in a nonfunctional installation

- Double click on the package of choice - the installation process will start. (N.B. the PREinstaller is very quick to complete whereas the full/upgrade installer will take longer.)

- Choose "standard install" when asked for installation type

- You may get a system message referring to "lipo command", and offering the option to install Xcode-related packages - choose not to install them, and disregard the message

- After installation, reboot the system

- After having completed both the PRE-installation and the full/upgrade installation, the usb interface can be reconnected

## NOTES

-----

- Application and data are kept local to the Home dir of the user who performed the installation

- Old application data (logbook database, settings) that may be present from previous installations, are preserved as much as possible
